[Legacy] Respondent Segmentation using a CSV file

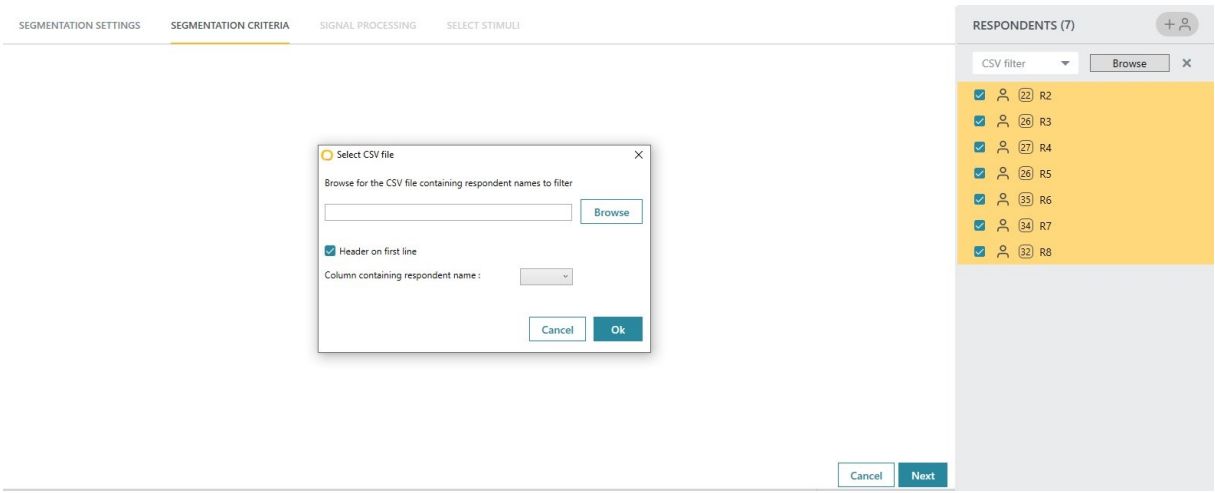

This article describes how you can choose specific respondents for your analysis based on using a csv file.

Once you have collected your data, you are able to add your analysis. Here you have the opportunity to choose a certain respondent group, based on various segmentation criteria.

The first step are the segmentation settings, allowing you to use the filter on the respondent panel to choose respondents based on name, age, or based on a csv filter.

If you want to use a csv file to automatically select certain respondents, choose csv filter in the drop down and click browse. A dialogue window will open up and you can choose a file you could like to use.

This file could come from a metrics export of that study or could have been created by you, either way, it needs to contain the desired respondent names in a column.

Here an example from the GSR Summary score export, where respondents R6, R7 and R8 have been removed, in order to select R2, R3, R4 and R5:

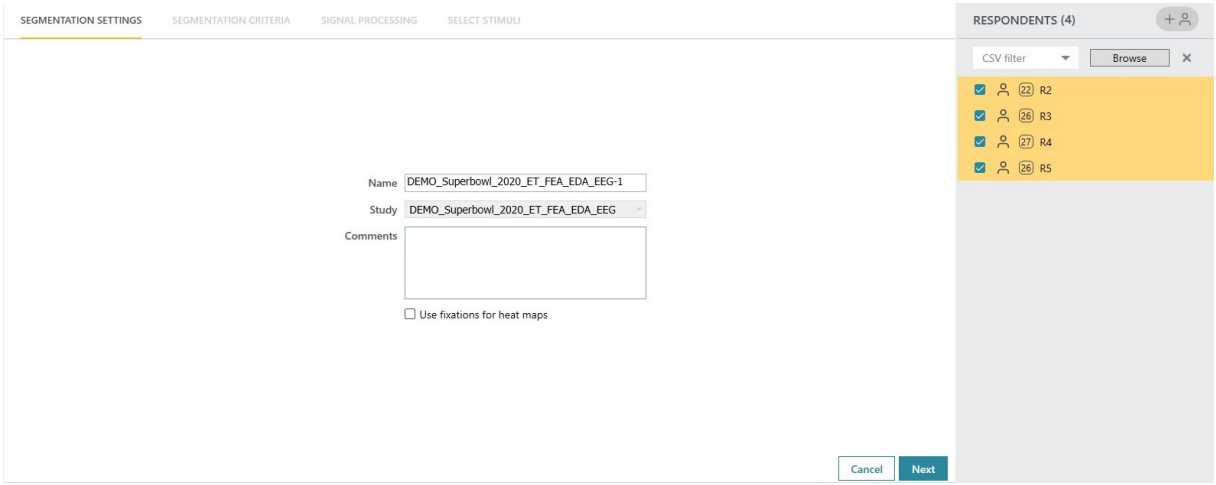

The respondent name is in column 2, hence that is what we will define in the dialogue window:

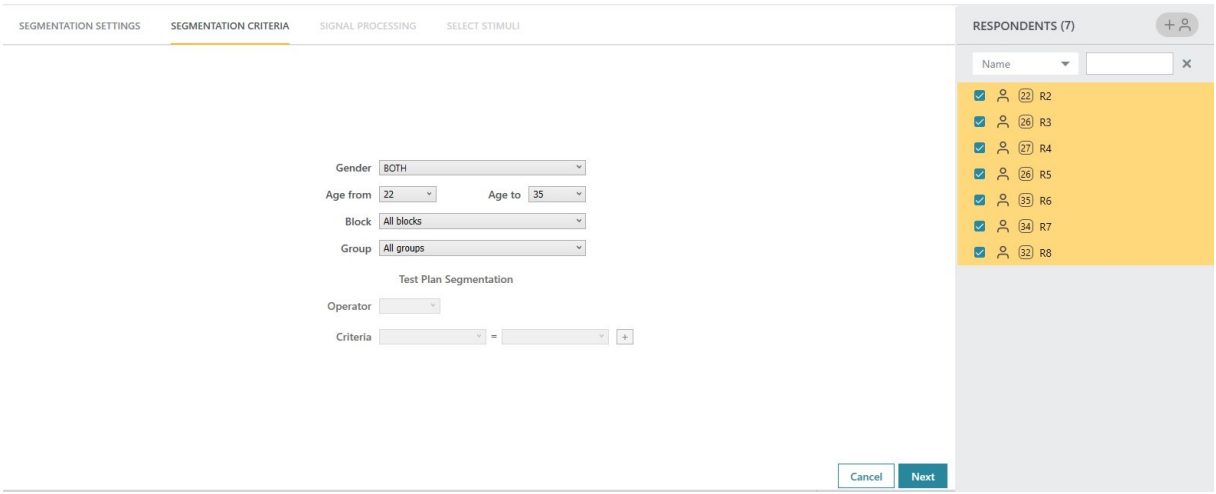

Once you click ok, the respondents as defined in the file are chosen and you can continue with the analysis by clicking next.

Now you can continue with the Segmentation criteria, where you have an additional option, so segment your analysis based on gender, age group, or groups you have defined.

One example where you would use both, segmentation settings and segmentation criteria, is to combine respondents with good data quality and then segment based on gender. Here you would have a csv/txt file with all respondents with good data quality that you would in general include in your analysis and use that for the segmentation settings and then choose all male or females during segmentation criteria to look at gender specific effects.
